# Data Mining Project 3

Ben Straub April 18th, 2017

#### Introduction

Mining activity has long been associated with mining hazards, such as fires, floods, and toxic contaminants (Dozolme, P., 2016). Among these hazards, seismic hazards are the hardest to detect and predict (Sikora & Wróbel, 2010). Minimizing loss from seismic hazards requires advanced data collection and analysis. In recent years, more and more advanced seismic and seismoacoustic monitoring systems have come about. Still, the disproportionate number of low-energy versus high-energy seismic phenomena (e.g.  $> 10^4$ J) renders traditional analysis methods insufficient.

To investigate these seismic hazards and explore more advance analysis technique we used the seismic-bumps dataset provided by Sikora & Wróbel (2010), found in the UCI Machine Learning Repository. This seismic-bumps dataset comes from a coal mine located in Poland and contains 2584 observations of 19 attributes. Each observation summarizes seismic activity in the rock mass within one 8-hour shift. Note that the decision attribute, named "class", has values 1 and 0. This variable is the response variable we use in this project. A class value of "1" is categorized as "hazardous state", which essentially indicates a registered seismic bump with high energy  $(>10^4 \text{J})$  in the next shift. A class value "0" represents non-hazardous state in the next shift. Table 1 in the Appendix has a listing of all 18 variables and their descriptions.

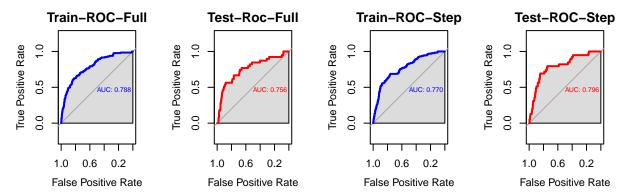

The purpose of this project is to find whether and how the other 18 variables can be used to determine the hazard status of the mine. In project 2, we utlized techniques such as the indicator matrix linear regression, logistic regression, linear discriminant analysis (LDA), quadratic discriminant qualysis (QDA), and regularized discriminant analysis (RDA) to try and find a model that would accurately predict the hazardous state. Unfortunately, all of the five project two methods performed poorly. We felt that there were two major issues at hand for this poor performance of the five methods. First, the low incidences of "1's" in the response variable class, which indicates a hazardous state in the mine. Only 170 "1's" for class out of 2584 were observed. A difficult problem for traditional method of analyses. The second issue was multicollinearity. Regression diagnostics indicate that the data, in general, meet most assumptions. However, we see that that data are somewhat skewed right, and there is severe multicollinearity (VIF > 10) between some of the covariates. Table 2 in the Appendix contains VIF's for the linear regression model.

Multicollinearity can be address by dimension reduction techniques such as PCA, step-wise regression, LASSO or ridge. In project 2, we utilized step-wise regression and LASSO to arrive at two candidate models. However, even with these dimension reduction techniques our models still performed poorly. Hopefully, to remedy this poor performance, we can utilize more advance techniques such as Boosting, Random Forest or Support Vector Machines.

In section 2, we report ROC curves and missclassification rates for Logistic Regression, LDA, QDA and RDA. In section 3, we report **best technique** out of the three that we tried. In section 4, we provide concluding remarks as well as future work on seismic data.

### Appendix

Table I. Attribute information of the seismic-bumps dataset

Data Attributes	Description
seismic	result of shift seismic hazard assessment: 'a' - lack of hazard, 'b' - low hazard, 'c' - high hazard, 'd
seismoacoustic	result of shift seismic hazard assessment
shift	type of a shift: 'W' - coal-getting, 'N' - preparation shift
genergy	seismic energy recorded within previous shift by active geophones (GMax) monitoring the longwal
gpuls	number of pulses recorded within previous shift by GMax
gdenergy	deviation of recorded energy within previous shift from average energy recorded during eight prev
gdpuls	deviation of recorded pulses within previous shift from average number of pulses recorded during
ghazard	result of shift seismic hazard assessment by the seismoacoustic method based on registration comi
nbumps	the number of seismic bumps recorded within previous shift
nbumps $i, i \in \{1, \dots, 5\}$	the number of seismic bumps $(10^i - 10^{i+1} \text{ J})$ registered within previous shift
energy	total energy of seismic bumps registered within previous shift
maxenergy	maximum energy of the seismic bumps registered within previous shift
class	the decision attribute: '1' - high energy seismic bump occurred in the next shift ('hazardous state
